Run the competition. Share every run.

Schedule. Submit. Score. Replay.

Created and maintained by **Peyman Yousefi**. Developed for and used in the RoboCupJunior Americas Super Regional 2026 Rescue Simulation competition.

A complete competition workspace

Public visitors follow the programme, scores, released maps and match replays. Teams receive a private workspace for submissions, organizer documents and complaints. Organizers manage the entire competition through one console.

Deployed reference: RCJRescue.com
Repository: github.com/peymanyousefi3/rcj-rescue-platform

All screenshots use fictional demonstration data. The repository remains private until its owner approves publication.

01 / Recording to interactive replay

Upload an Erebus/Webots folder or ZIP. Assets retain their names and relative paths in an isolated package. A preview and Play button open a responsive popup with the exported player, seeking, camera navigation and fullscreen. A video can also be supplied.

The recording metadata fills score and time only where those fields are empty. Final score already includes bonuses. Existing manual values are preserved. Exported event scripts follow the playback timeline rather than showing the final event throughout the run.

02 / Round lineup to calendar

Arrange the teams within a round. Place its block in the calendar and individual run times follow the lineup. Drag an event to move it, click to edit in a popup, or select an empty interval to add an activity.

03 / Scores to reviewed standings

Enter scores in a team-by-round matrix, paste from a spreadsheet, undo edits and spot missing values. Main and SuperTeam score tables appear together. Rank publication requires an administrator decision even when scores are already public.

Default field calculation: normalize each round against its highest raw score, discard each team's configured number of lowest normalized scores, then average the retained scores and multiply by 100. Keep at least one round. Exact ties remain ties unless a tie-break is configured; zero-maximum rounds require an organizer decision.

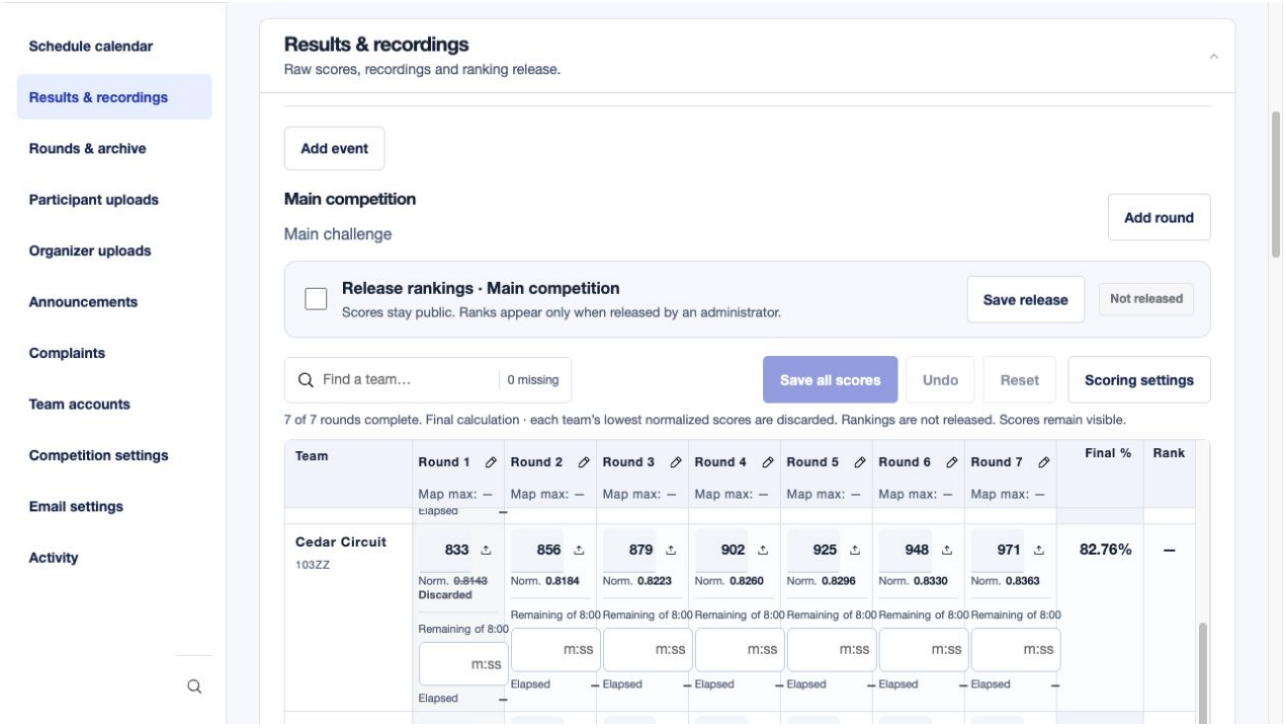

04 / Controlled access and communication

Named quarantine requests support team-specific deadlines and private multi-file submissions. Organizer packages and announcements use one record with a recipient list. Search, select all and clear controls make audience selection direct. Removing a recipient removes permission.

Additional tools include map-folder detection, metadata and GLB views; SuperTeam pairings using existing teams; complaint attachments and organizer responses; account management; optional personalized email; storage configuration and activity records.

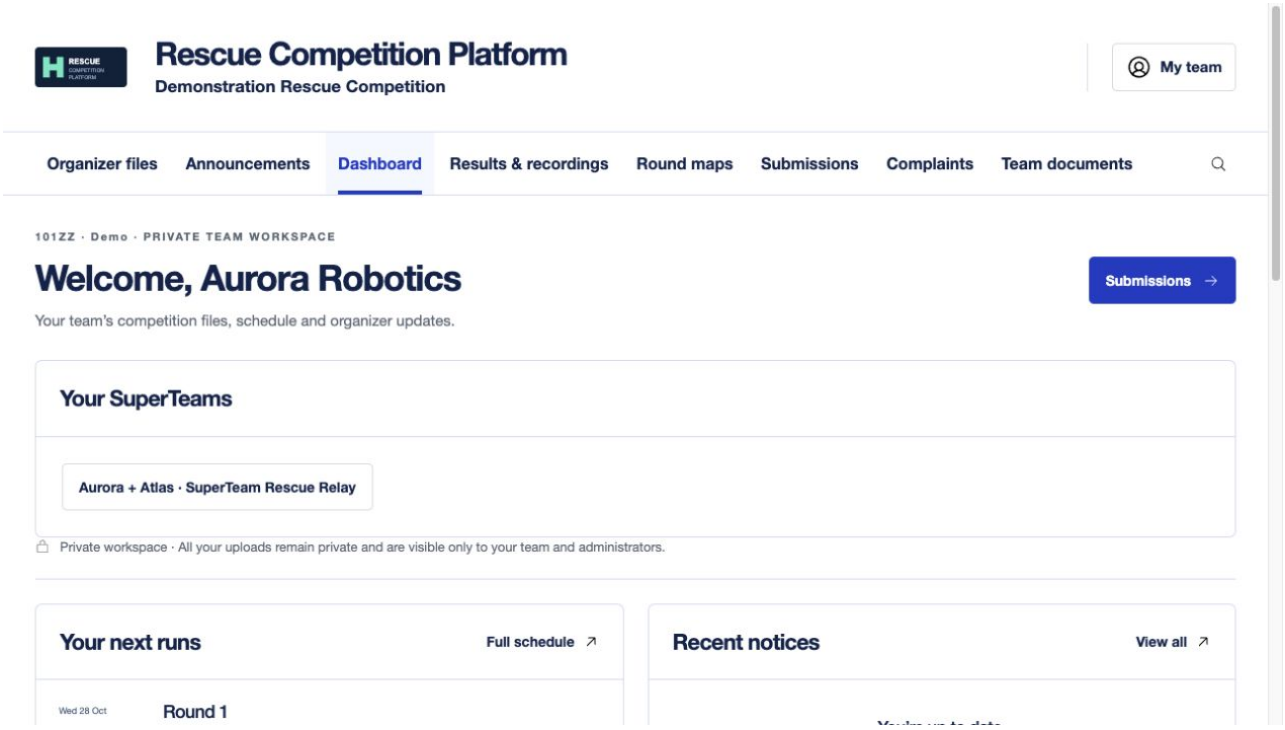

Missing recording metadata does not become a zero result. Older recordings remain playable. Public release and team privacy remain separate decisions.

Organizer scoring

A single matrix keeps scores, recordings, normalized values, discards and rank release together.

Team workspace

A team sees its own workspace, upcoming runs and shared SuperTeam access.

Get started

Use Python 3.12 for development, or Docker Compose for the application, PostgreSQL, scanner and background worker. The setup guide provides commands for a fresh installation. Create your own administrator account; no shared account or password is bundled.

The optional demo command creates fictional teams, scores and a SuperTeam challenge. It sends no email and creates no login accounts. Do not run it on a real competition database.

Before operating a real event

Configure the event dates, timezone, challenges and scoring policies. Set up teams, lineups, upload windows and recipients. Configure SMTP and storage outside version control. Use HTTPS, restricted private storage, malware scanning and tested backups. Review release settings before publishing maps, recordings or rankings.

Private review and source preparation

The separate repository uses a new source history. The original database, participant accounts, submissions, recording packages, environment secrets and production operational notes are excluded. Screenshots come from an isolated fictional local demo. The deployed competition has not been changed for this preparation.

Verification: all 358 Python tests passed on PostgreSQL, including concurrency checks, plus all 10 JavaScript checks. Production checks and dependency and secret scans passed. Passing checks are not a guarantee of complete security.
